

ETH zürich

Use of miniature drones for biodiversity survey

Prof. Dr. Stefano Mintchev

Environmental Robotics Lab

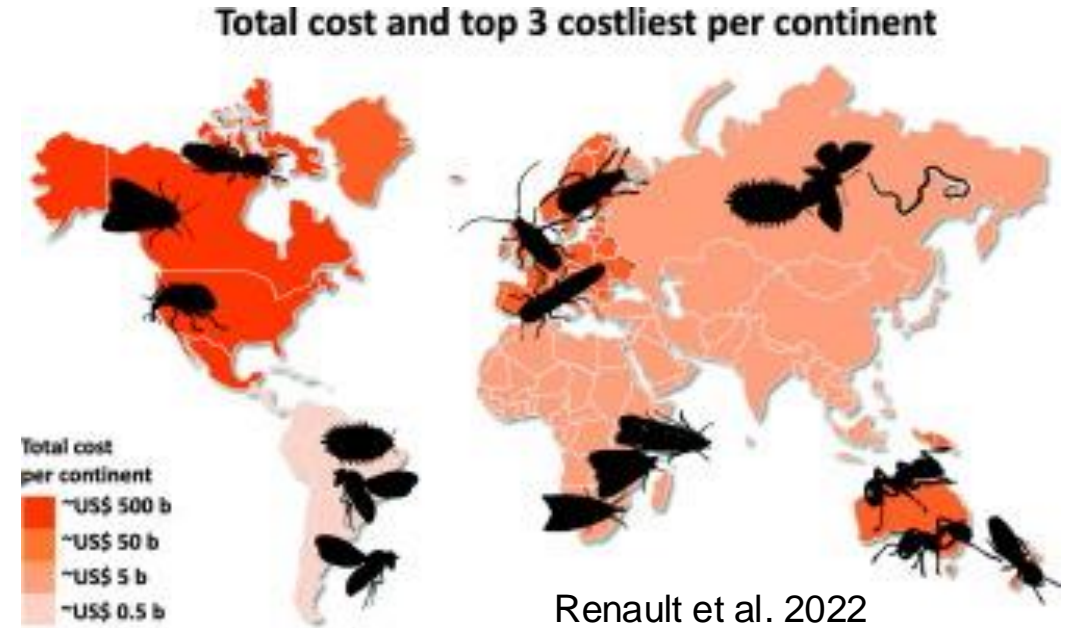

23 Oct 2024

Motivation

Globalisation and climate change have led to an **increase in pest invasions** and outbreaks worldwide, causing significant crop losses and economic damages.

- These costs are rising and were mostly due to invasive insects (88%)
- These costs mainly resulted from direct resource damages and losses (75%)

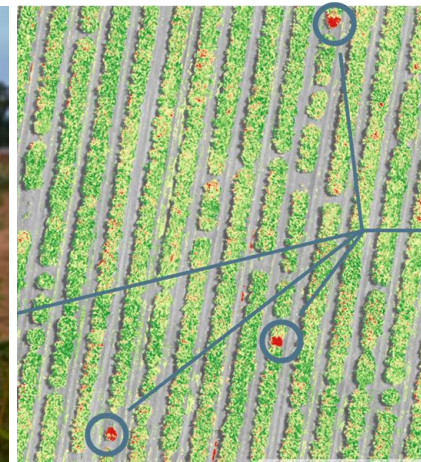

Traditional **monitoring approaches** are **inadequate** in detecting invasions or outbreaks during their **early stages**, when management protocols are most effective and sustainable.

Visual survey

Camera / pheromone traps

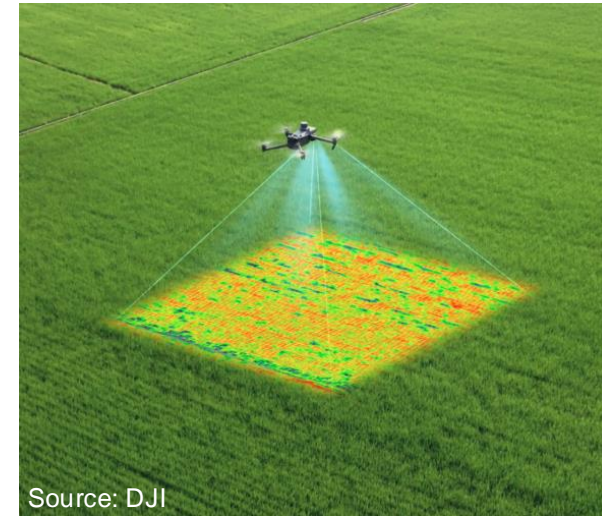

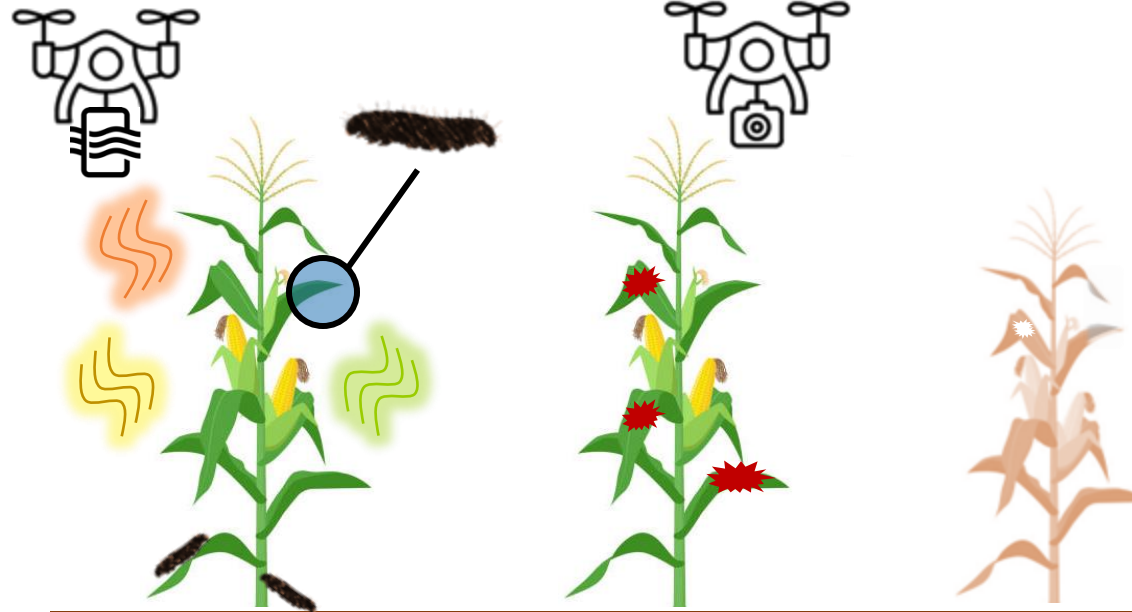

Remote sensing

Early pest detection for sustainable agriculture

Plant volatiles for remote sensing of insect pests

Attract predators and parasitoids
(Kessler & Baldwin 2001, Brodman et al. 2008)

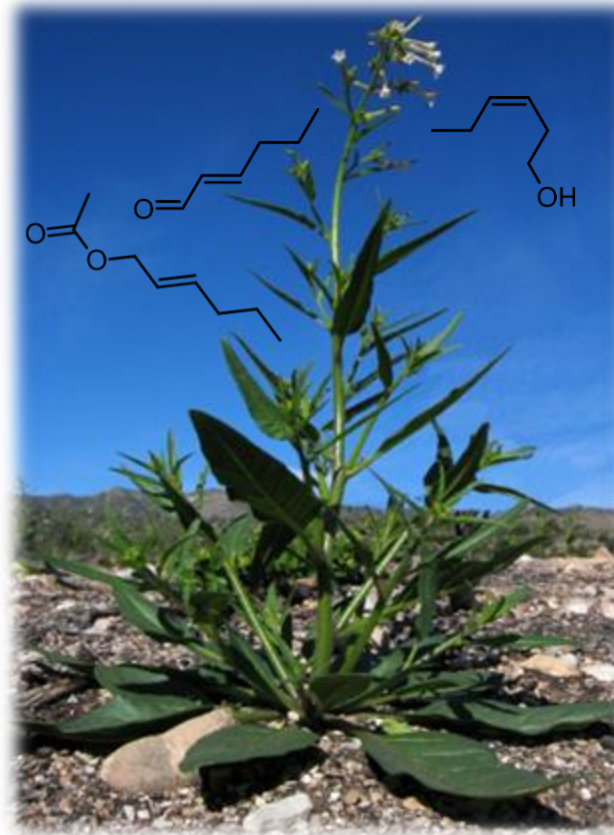

Repel adult herbivores
(Allmann et al. 2013)

What make volatiles an excellent early warning system?

- *Rapid* (released withing seconds / hours)
- *Predictable* (provide info about the physiological and phenological status of the plant)
- *Tailored* (mixture and ratio depends on the herbivore)

Plant volatiles ...

... collection

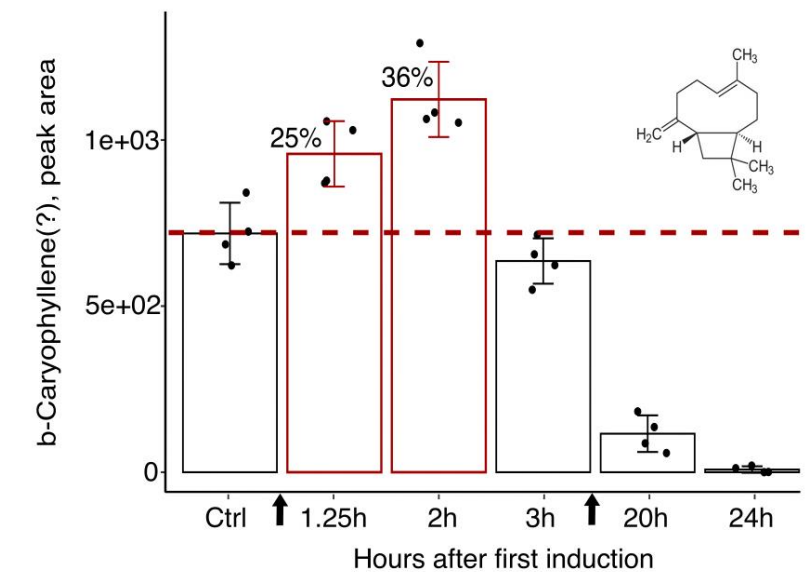

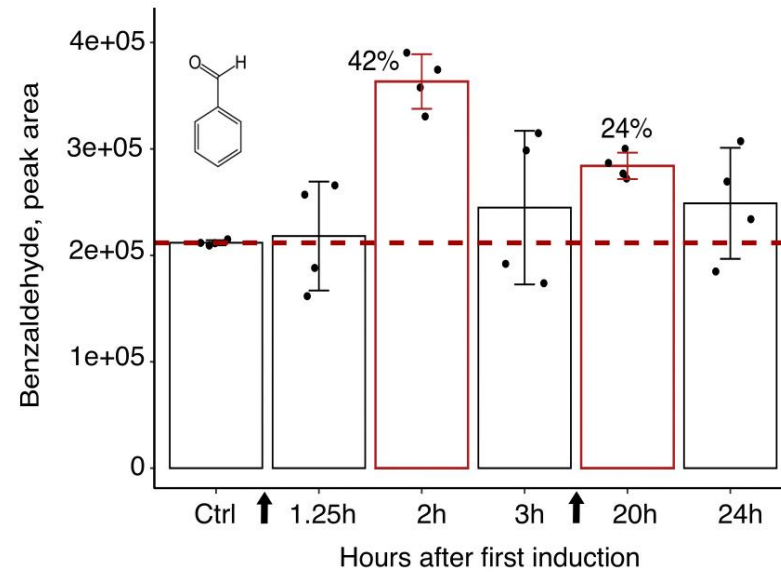

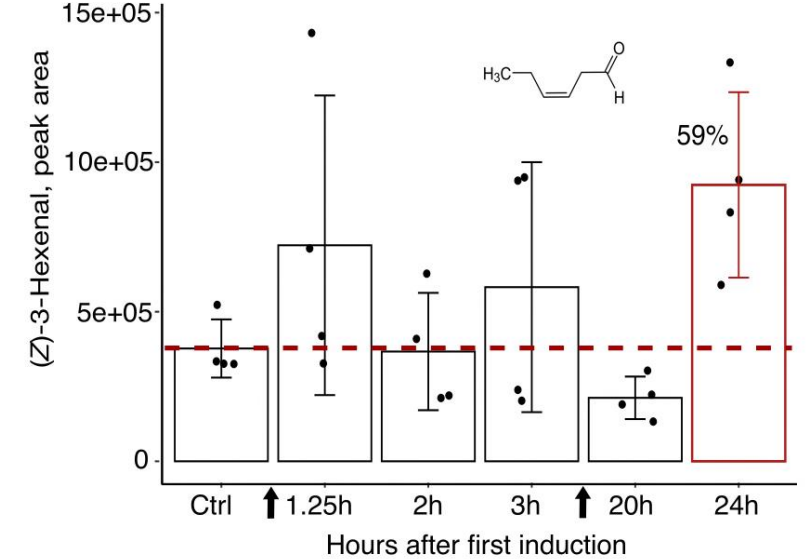

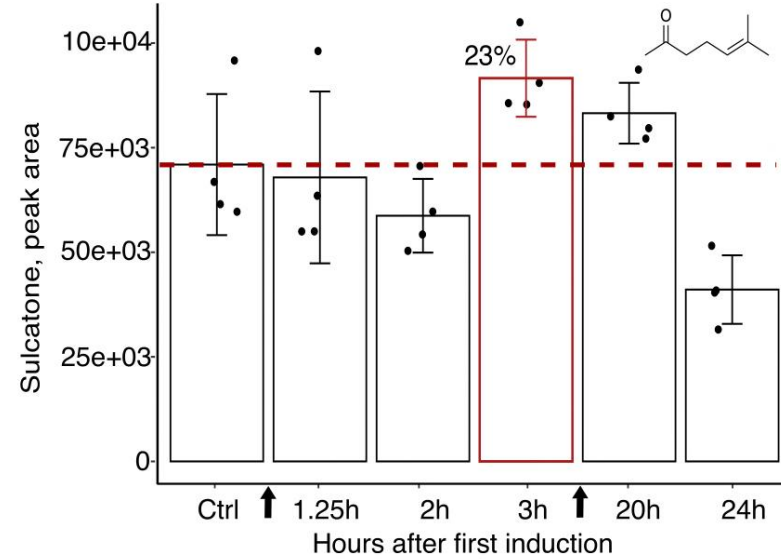

Drone-base collection of plant volatiles

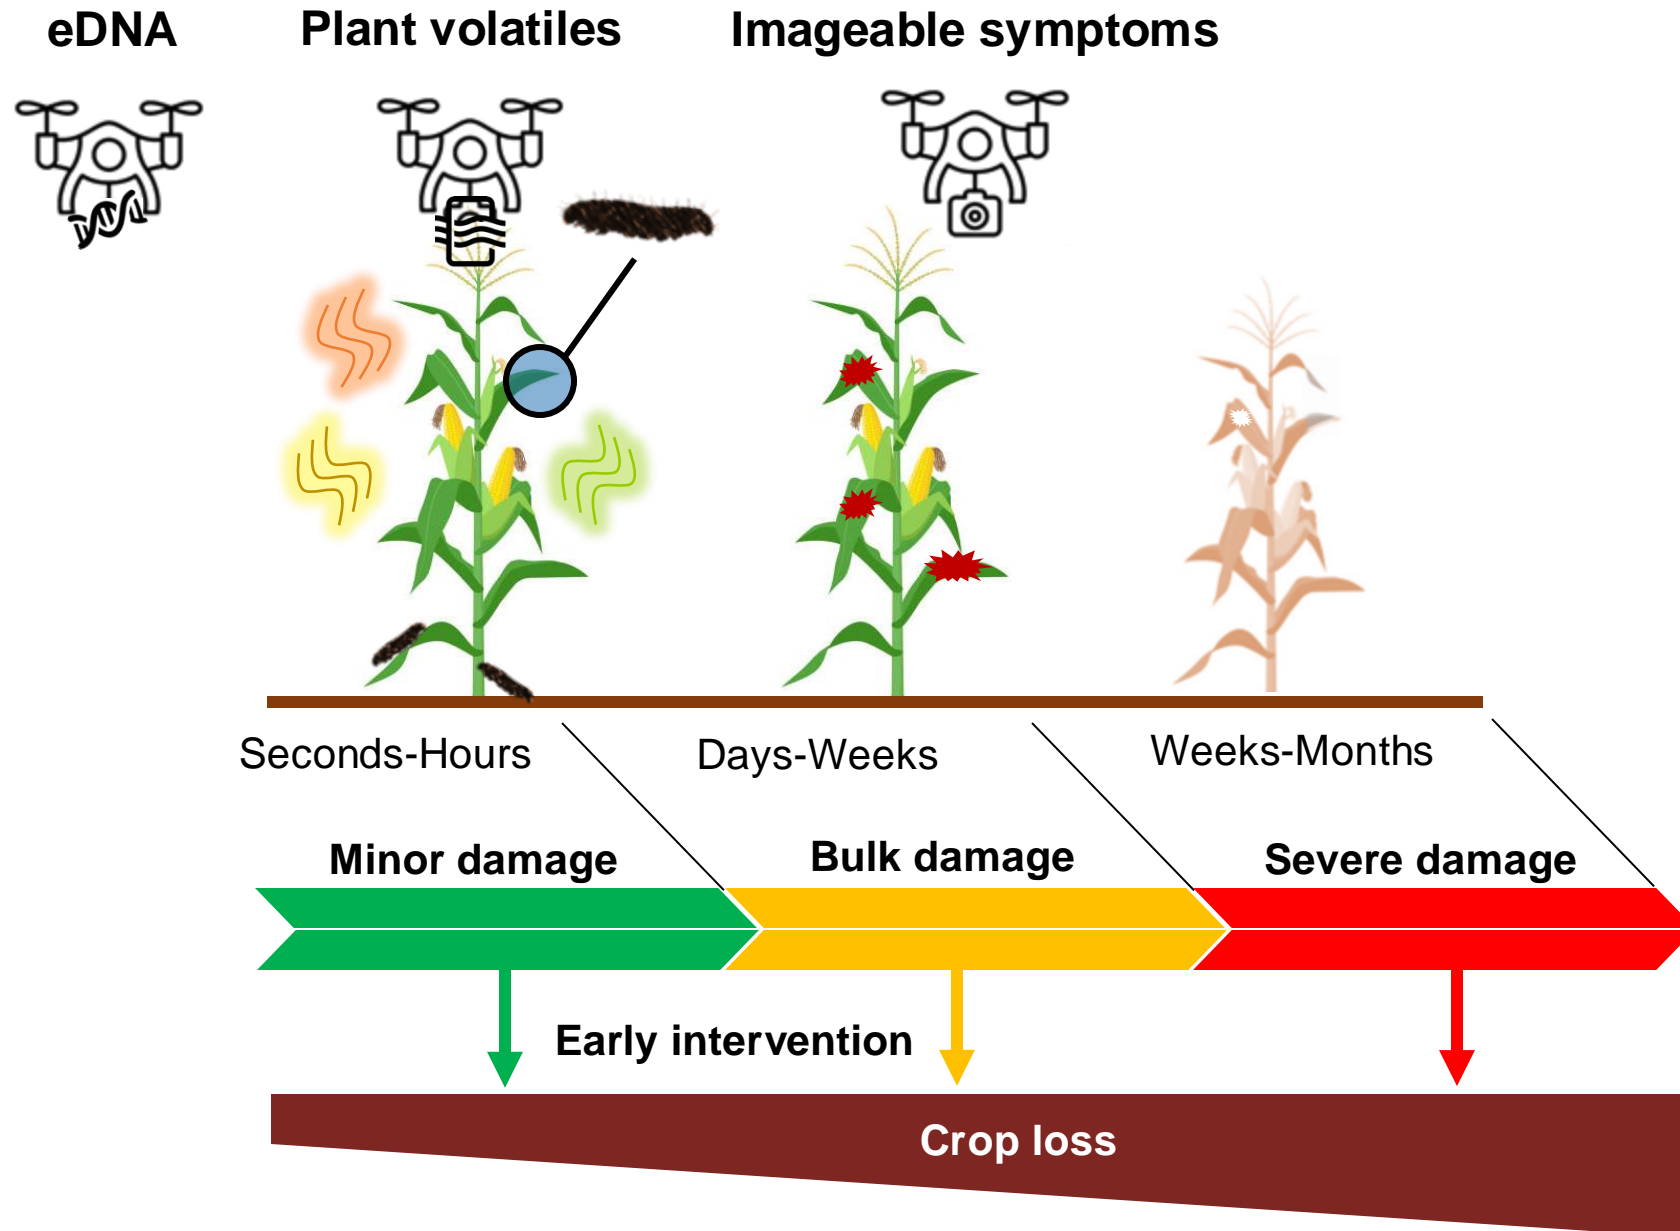

Outdoor Deployment

Proof-of-concept outdoor sampling

Early pest detection for sustainable agriculture

Environmental DNA

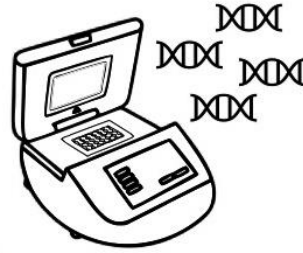

eDNA collection

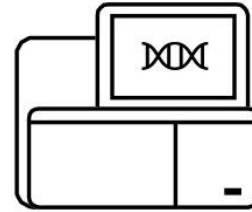

DNA extraction

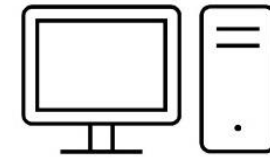

DNA amplification

Sequencing

Bioinformatics

Results

Valentin et al. 2019, Allen et al. 2020

State-of-the art and limitations

Survey tools based on eDNA have proven especially useful for detecting rare or elusive species due to their high sensitivity to detect minute traces left behind by organisms.

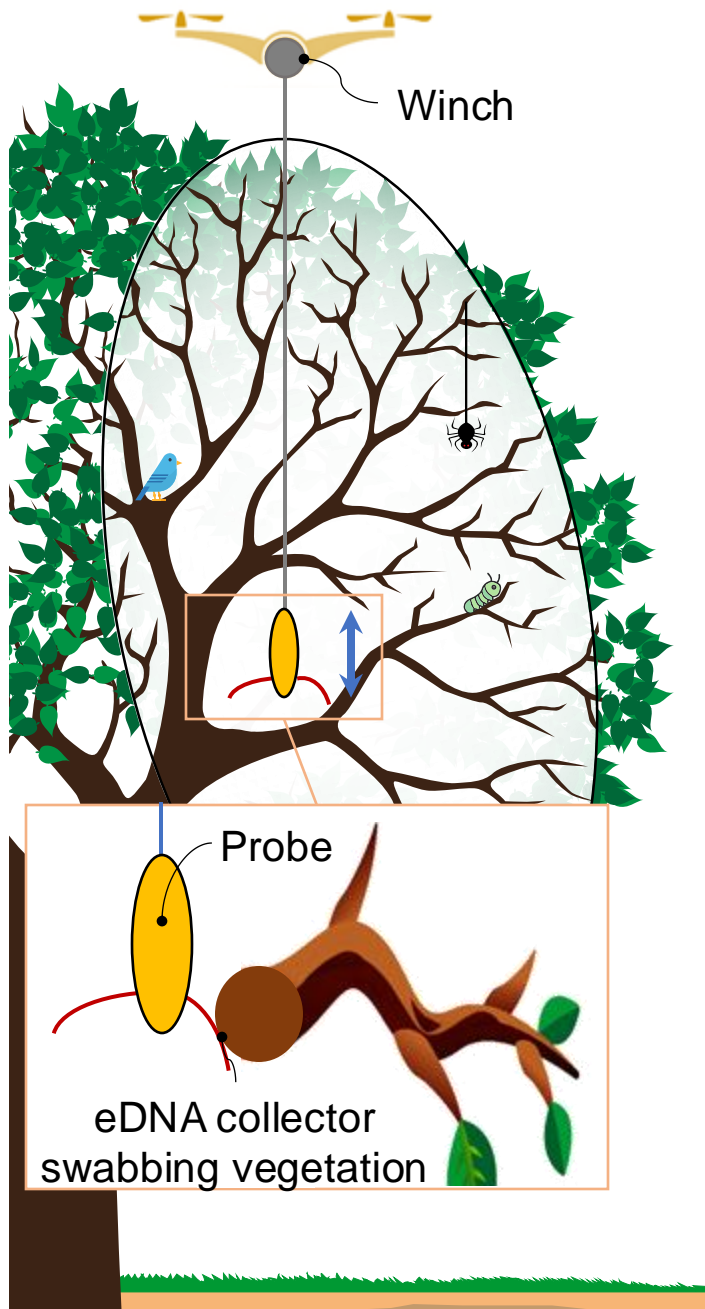

Valentin et al. 2019, Allen et al. 2020

The probability of detecting spotted lanternflies given presence in a plot was over two times higher for eDNA (84%) versus visual surveys (36%).

Limitations

- 1) Manual eDNA collection is labor intensive, time-consuming (2 m/min) and not repeatable.
- 2) Processing samples can be expensive and time-consuming.

eProbe - Surface eDNA Sampling

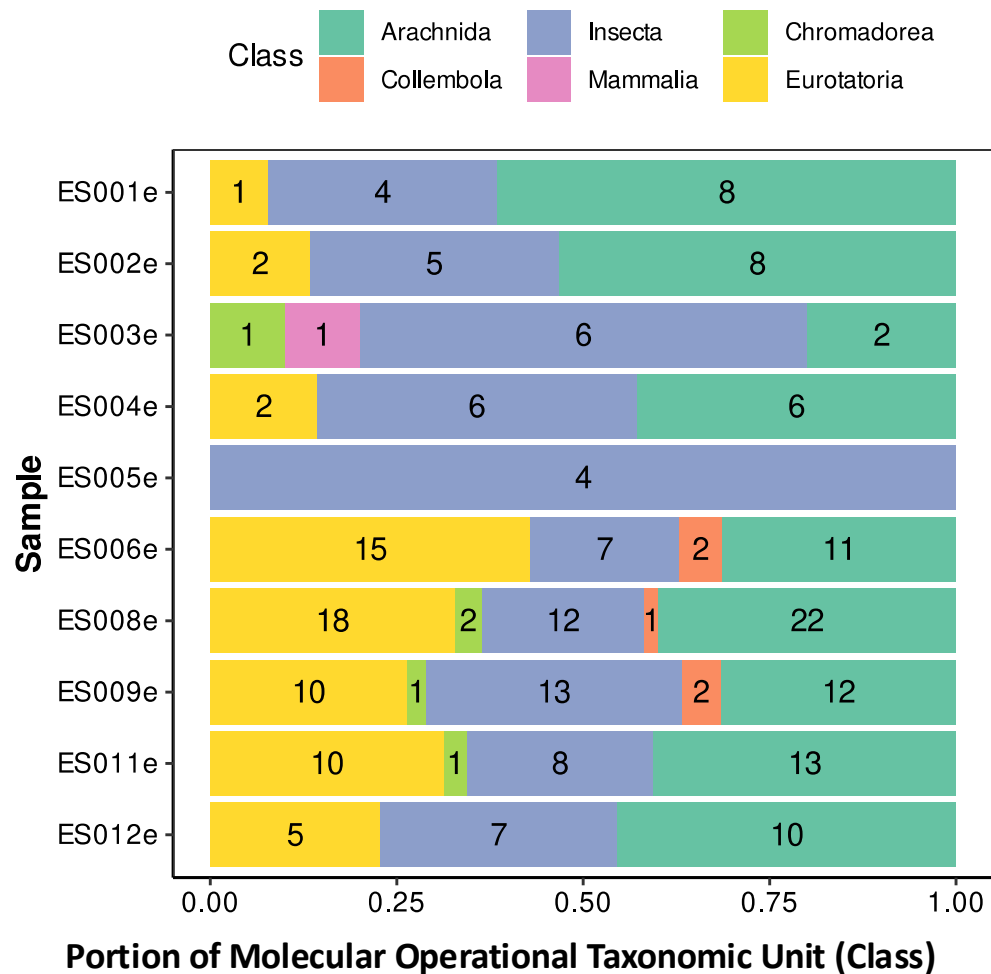

S. Kirchgeorg, et al., "eProbe: Sampling of Environmental DNA within Tree Canopies with Drones", Environmental Science and Technology, 2024.

Results - eDNA Survey in Singapore

of probes = 10

of metazoan detections = 152

Macaca fascicularis

Hospitalitermes sp

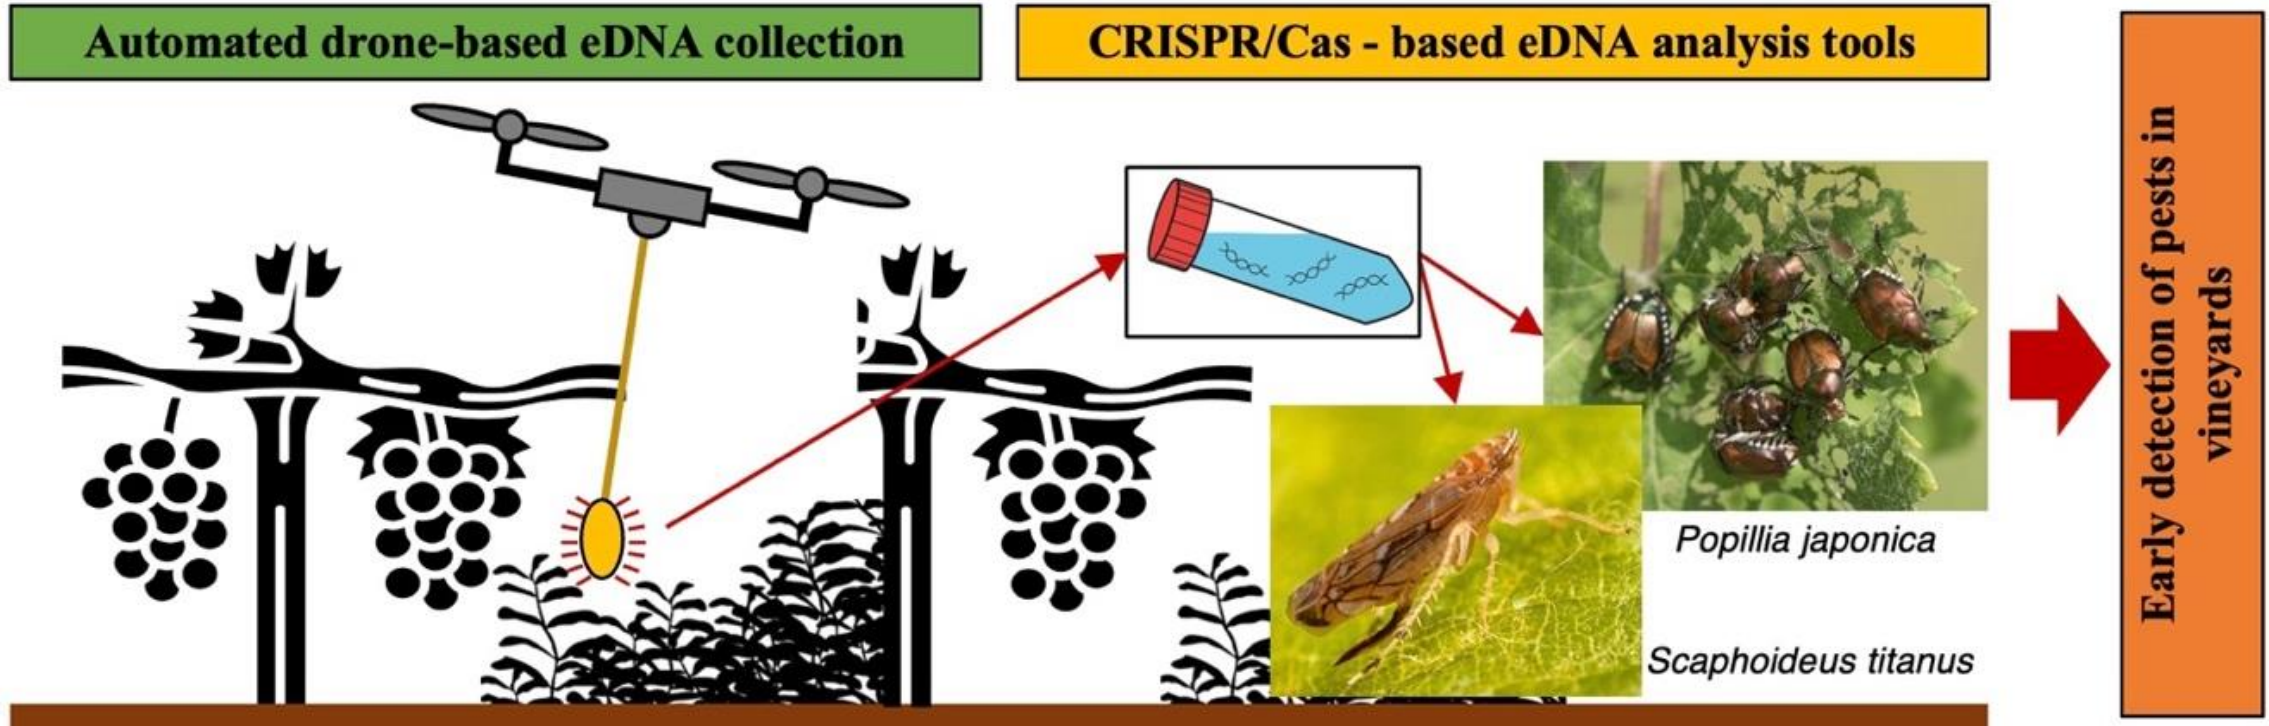

Cecidomyiidae sp.

Entomobrya marginata

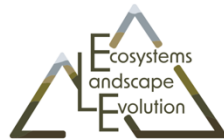

The GRiP Project

This interdisciplinary research project aims to **improve the sensitivity and timeliness** of pest detection and surveillance in Swiss vineyards through the integration of **robotics and genetic technologies**.

In collaboration with:

- Prof. Loïc Pellissier
- Dr. Martina Lüthi

fenaco

Filed tests in vineyards

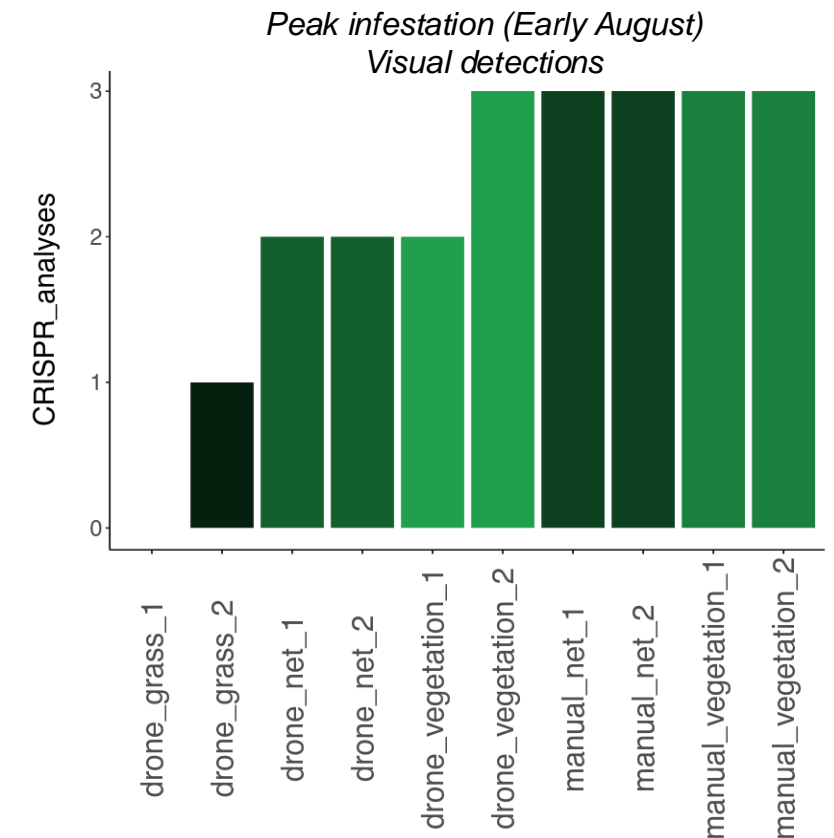

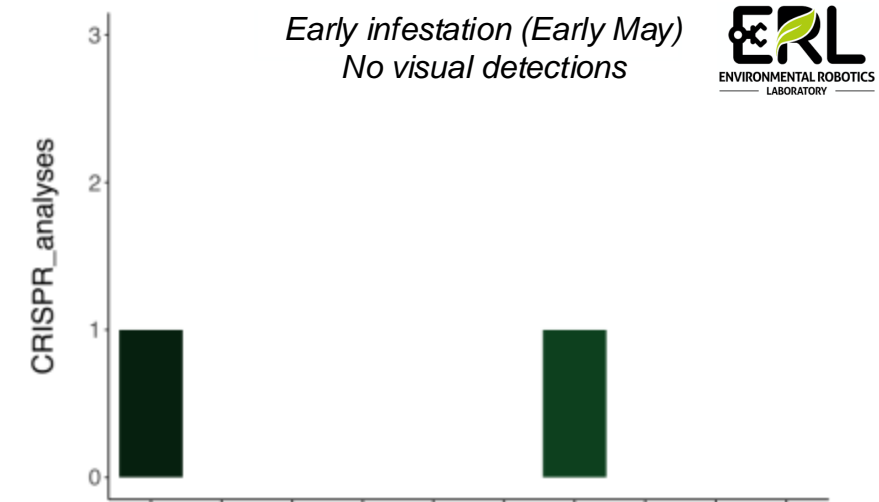

Successfully developed and tested:

- Drone-based eDNA sampling
- CRISPR_cas detection of *P. japonica*

Collection of dataset to compare eDNA sampling (drone and manual) with visual survey
